We show exactly that the squared entanglement of formation (SEF) obeys a set of hierarchical monogamy relations for an arbitrary  $N$ -qubit mixed state. Based on this set of monogamy relations, we are able to construct the set of hierarchical multipartite entanglement indicators for  $N$ -qubit states, which still work well even when the concurrence-based indicators lose efficacy. As a by-product, an intriguing analytical relation between the entanglement of formation (EOF) and squared concurrence (SC) for an arbitrary mixed state of  $2 \otimes d$  systems is derived, making the concurrence calculable via the corresponding EOF. Furthermore, we analyze the multipartite entanglement dynamics in composite cavity-reservoir systems with the present set of hierarchical indicators. Moreover, for multilevel systems, it is illustrated that the SEF can be monogamous even if the SC is polygamous.

## I. INTRODUCTION

Entanglement monogamy is one of the most important properties for many-body quantum systems [1, 2], which means that quantum entanglement cannot be freely shared among many parties and there is a trade-off among the amount of entanglement in different subsystems. For example, in a three-qubit system  $\rho_{ABC}$ , when qubits  $A$  and  $B$  are maximally entangled, the third qubit  $C$  cannot be correlated with qubits  $AB$  at all [3]. For entanglement quantified by the squared concurrence (SC) [4], Coffman *et al.* proved the first quantitative monogamy relation for three-qubit states [5], *i.e.*,  $C^2(\rho_{A|BC}) - C^2(\rho_{AB}) - C^2(\rho_{AC}) \geq 0$ , and the residual entanglement can be used to characterize the genuine three-qubit entanglement [6]. Furthermore, Osborne and Verstraete proved the corresponding relation for  $N$ -qubit systems [7]  $C^2(\rho_{A_1|A_2 \dots A_N}) - C^2(\rho_{A_1 A_2}) - \dots - C^2(\rho_{A_1 A_N}) \geq 0$ , in which  $C^2(\rho_{A_1|A_2 \dots A_N})$  characterizes bipartite entanglement in the partition  $A_1|A_2 \dots A_N$  and  $C^2(\rho_{A_1 A_i})$  quantifies two-qubit entanglement with  $i = 2, 3, \dots, N$ . As is known, the entanglement monogamy property can be used to characterizing multipartite entanglement structure [5–7], based on which some multipartite entanglement measures and indicators are introduced and utilized to detect the existence of multiqubit entanglement in dynamical procedures [8–16]. Similar monogamy relations were also generalized to Gaussian systems [17, 18], squashed entanglement [19, 20], entanglement negativity [21–23], entanglement Renyi entropy [24, 25], Lorentz invariance [26] and strong entanglement monogamy cases [27–29].

The entanglement of formation (EOF) is also a well-defined bipartite entanglement measure and has operational meaning in entanglement preparation and data storage [3]. Unfortunately, EOF itself does not satisfy the usual monogamy rela-

tion even for three-qubit pure states. Recently, it was indicated that the squared entanglement of formation (SEF) obeys the monogamy relation in multiqubit systems [30–33]. In particular, we proved analytically that the SEF is monogamous in an arbitrary  $N$ -qubit mixed state and obeys the relation [32]

$$E_f^2(\rho_{A_1|A_2 \dots A_N}) - E_f^2(\rho_{A_1 A_2}) - \dots - E_f^2(\rho_{A_1 A_N}) \geq 0. \quad (1)$$

In comparison with the  $N$ -qubit monogamy relation for SC [7], the advantages of that for SEF shown in Eq. (1) are that (i) the residual entanglement of SEF can indicate all multi-qubit entangled states in the  $N$ -partite systems [32] and (ii) unlike the concurrence  $C(\rho_{A_1|A_2 \dots A_N})$ , the multiqubit EOF  $E_f(\rho_{A_1|A_2 \dots A_N})$  can be calculated via quantum discord [34–38] without resorting to the convex roof extension [39].

Osborne and Verstraete proved that When an  $N$ -qubit quantum state is divided into  $k$  parties, Osborne and Verstraete proved that the SC obeys a set of hierarchical monogamy relations [7],

$$C^2(\rho_{A_1|A_2 \dots A_N}) \geq \sum_{i=2}^{k-1} C^2(\rho_{A_1 A_i}) + C^2(\rho_{A_1|A_k \dots A_N}), \quad (2)$$

which can be used to detect the multipartite entanglement in  $k$ -partite cases with  $k = \{3, 4, \dots, N\}$ . However, calculating multiqubit concurrence is extremely hard due to the convex roof extension [39], which makes the quantitative characterization on this set of monogamy relations very difficult. Since the  $N$ -partite monogamy relation of SC has an intrinsic relation with that of SEF [32], it is natural to ask whether or not the SEF in  $k$ -partite systems satisfies similar hierarchical monogamy relations, considering that the bipartite multiqubit EOF is calculable via effective methods for calculating quantum discord [40–49]. Moreover, is the amount of EOF related to that of SC in multiqubit systems (and, if so, how)? On the other hand, whether the monogamy properties of SEF and SC are equivalent in general multipartite systems still seems to be a fundamental open question.

In this paper, we show exactly that the SEF obeys a set of hierarchical  $k$ -partite monogamy relations in an arbitrary

$N$ -qubit mixed state. Based on these monogamy relations, a set of hierarchical multipartite entanglement indicators which can still work well even when the concurrence-based indicators lose their efficacy is constructed correspondingly. As a byproduct, we also obtain the analytical relation between EOF and SC in  $2 \otimes d$  systems. Furthermore, we analyze the multipartite entanglement dynamics in cavity-reservoir systems with the presented hierarchical indicators. Finally, we make a comparative study of the monogamy properties of SEF and SC, which are inequivalent in multi-level systems.

## II. HIERARCHICAL $K$ -PARTITE MONOGAMY RELATIONS FOR SEF IN $N$ -QUBIT SYSTEMS

In a bipartite mixed state  $\varrho_{AB}$ , the EOF is defined as [39]

$$E_f(\varrho_{AB}) = \min_i \sum p_i E_f(|\psi^i\rangle_{AB}), \quad (3)$$

where  $E_f(|\psi^i\rangle_{AB}) = S(\rho_A^i) = -\text{Tr} \rho_A^i \log_2 \rho_A^i$  is the von Neumann entropy and minimum running over all the pure state decompositions. In particular, for two-qubit states, an analytical formula was given by Wootters [50]

$$E_f(\rho_{AB}) = h\left(\frac{1 + \sqrt{1 - C_{AB}^2}}{2}\right), \quad (4)$$

where  $h(x) = -x \log_2 x - (1-x) \log_2 (1-x)$  is the binary entropy and  $C_{AB} = \max\{0, \sqrt{\lambda_1} - \sqrt{\lambda_2} - \sqrt{\lambda_3} - \sqrt{\lambda_4}\}$  is the concurrence, with  $\lambda_i$  being the decreasing eigenvalues of matrix  $\rho_{AB}(\sigma_y \otimes \sigma_y) \rho_{AB}^*(\sigma_y \otimes \sigma_y)$ .

In this work, a key result is to show exactly a set of hierarchical  $k$ -partite monogamy relations for SEF in arbitrary  $N$ -qubit mixed states  $\rho_{A_1 A_2 \dots A_N}$ ,

$$E_f^2(\rho_{A_1 | A_2 \dots A_N}) \geq \sum_{i=2}^{k-1} E_f^2(\rho_{A_1 A_i}) + E_f^2(\rho_{A_1 | A_k \dots A_N}) \quad (5)$$

for  $k = \{3, 4, \dots, N\}$ , where the relation for  $k = N$  is just the above-mentioned monogamy inequality of Eq. (1). To show this set of monogamy relations of SEF, we first prove the following lemmas and theorems.

**Lemma 1.** For two-qubit mixed states, the entanglement of formation  $E_f(C^2)$  is monotonic and concave as a function of squared concurrence  $C^2$ .

*Proof.* The monotonically increasing property of  $E_f(C^2)$  is satisfied if the first-order derivative  $dE_f/dx > 0$ , with  $x = C^2$ . According to Eq. (4), we have

$$\frac{dE_f}{dx} = \frac{1}{\sqrt{1-x} \cdot \ln 16} \ln\left(\frac{1 + \sqrt{1-x}}{1 - \sqrt{1-x}}\right). \quad (6)$$

When  $x \in (0, 1)$ , the first-order derivative is positive. Combining this fact with the observation that  $E_f(0) = 0$  and  $E_f(1) = 1$  correspond respectively to its minimum and maximum, we can deduce that  $E_f$  is a monotonically increasing function of  $x$ . Moreover, the concave property of  $E_f(x)$  holds

if the second-order derivative  $d^2 E_f/dx^2 < 0$ . After some deduction, we have

$$\frac{d^2 E_f}{dx^2} = g(x) \cdot \{-2\sqrt{1-x} + x \cdot \ln\left(\frac{1 + \sqrt{1-x}}{1 - \sqrt{1-x}}\right)\} < 0, \quad (7)$$

where  $g(x) = 1/[2 \cdot (\ln 16) \cdot x(1-x)^{3/2}]$  is a nonnegative factor. Therefore, the entanglement of formation  $E_f$  is a concave function of  $x$ . The details for illustrating the negativity of Eq. (7) are presented in Appendix A.

**Lemma 2.** For two-qubit mixed states, the entanglement of formation  $E_f(C)$  is monotonic and convex as a function of concurrence  $C$ .

*Proof.* The monotonically increasing property of  $E_f(C)$  is satisfied if the first-order derivative  $dE_f/dC > 0$ . According to Eq. (4), we have

$$\frac{dE_f}{dC} = \frac{C}{\sqrt{1-C^2} \cdot \ln 4} \ln\left(\frac{1 + \sqrt{1-C^2}}{1 - \sqrt{1-C^2}}\right). \quad (8)$$

When  $C \in (0, 1)$ , the first-order derivative is positive. Combining this fact with an observation that  $E_f(0) = 0$  and  $E_f(1) = 1$  correspond respectively to its minimum and maximum, we can deduce that  $E_f$  is a monotonically increasing function of  $C$ . Furthermore, the convex property of  $E_f(C)$  holds if the second-order derivative  $d^2 E_f/dC^2 > 0$ . After some deduction, we have

$$\frac{d^2 E_f}{dC^2} = u(C) \cdot \{-2\sqrt{1-C^2} + \ln\left(\frac{1 + \sqrt{1-C^2}}{1 - \sqrt{1-C^2}}\right)\} > 0, \quad (9)$$

where  $u(C) = 1/[(\ln 4) \cdot (1-C^2)^{3/2}]$  is a non-negative factor. Therefore, the entanglement of formation  $E_f$  is a convex function of  $C$ . The details for proving the positivity of Eq. (9) are shown in Appendix B.

**Theorem 1.** For a bipartite  $2 \otimes d$  mixed state  $\rho_{AC}$ , the entanglement of formation obeys the following relation

$$E_f(\rho_{AC}) = E_f[C^2(\rho_{AC})], \quad (10)$$

where the function on the right-hand side has the same expression as that of two-qubit EOF shown in Eq. (4) with  $C^2$  being the squared concurrence of  $2 \otimes d$  systems.

*Proof.* According to Eq. (3), the EOF in  $2 \otimes d$  systems has the form  $E_f(\rho_{AC}) = \min_i \sum p_i E_f(|\psi^i\rangle_{AC})$ . Under the optimal pure state decomposition  $\{p_i, |\psi^i\rangle_{AC}\}$ , we have

$$\begin{aligned} E_f(\rho_{AC}) &= \sum_i p_i E_f(|\psi^i\rangle_{AC}) \\ &= \sum_i p_i E_f[C^2(|\psi^i\rangle_{AC})] \\ &\leq \sum_j q_j E_f[C^2(|\varphi^j\rangle_{AC})] \\ &\leq E_f\left[\sum_j q_j C^2(|\varphi^j\rangle_{AC})\right] \\ &= E_f[C^2(\rho_{AC})], \end{aligned} \quad (11)$$

where we have used in the second equality the Wootters formula for pure states since the  $2 \otimes d$  pure state  $|\psi^i\rangle_{AC}$  is

equivalent to a two-qubit state under Schmidt decomposition [51] and have taken the EOF  $E_f(|\psi^i\rangle_{AC})$  as a function of the squared concurrence  $C^2(|\psi^i\rangle_{AC})$ , and in the third inequality the optimal decomposition  $\{q_j, |\varphi^j\rangle_{AC}\}$  for the concurrence  $C^2(\rho_{AC}) = \min \sum_j q_j C^2(|\varphi^j\rangle_{AC})$  [7], which results in the average EOF being not less than  $E_f(\rho_{AC})$ . The fourth inequality holds because of the concave property of  $E_f(C^2)$  as proved in Lemma 1, and the last equality is satisfied because  $\{q_j, |\varphi^j\rangle_{AC}\}$  is the optimal pure-state decomposition for  $C^2(\rho_{AC})$ . On the other hand, under the optimal pure-state decomposition of  $E_f(\rho_{AC})$ , we also have

$$\begin{aligned} E_f(\rho_{AC}) &= \sum_i p_i E_f(|\psi^i\rangle_{AC}) \\ &= \sum_i p_i E_f[C(|\psi^i\rangle_{AC})] \\ &\geq E_f[\sum_i p_i C(|\psi^i\rangle_{AC})] \\ &\geq E_f[\sum_k r_k C(|\phi^k\rangle_{AC})] \\ &= E_f[C(\rho_{AC})], \end{aligned} \quad (12)$$

where, we have used in the second equality the Wootters formula for pure states and have taken the EOF  $E_f(|\psi^i\rangle_{AC})$  as a function of the concurrence  $C(|\psi^i\rangle_{AC})$ , in the third inequality we have used the convex property of  $E_f(C)$  (proved in Lemma 2) as a function of concurrence  $C$ , and in the fourth inequality we have used the optimal pure-state decomposition  $\{r_k, |\phi^k\rangle_{AC}\}$  for the concurrence  $C(\rho_{AC})$  and the monotonically increasing property of  $E_f(C)$ . Combining Eq. (11) with Eq. (12), we can obtain

$$E_f[C(\rho_{AC})] \leq E_f(\rho_{AC}) \leq E_f[C^2(\rho_{AC})]. \quad (13)$$

Furthermore, according to the Wootters formula in Eq. (4), we have

$$E_f[C(\rho_{AC})] = h\left(\frac{1 + \sqrt{1 - C_{AC}^2}}{2}\right) = E_f[C^2(\rho_{AC})], \quad (14)$$

where  $E_f[C(\rho_{AC})] = E_f[C^2(\rho_{AC})]$  since they have the same expression, with  $h(x)$  being the binary entropy function. Therefore, the inequality signs in Eq. (13) become equality signs, and then Theorem 1 is satisfied.

**Theorem 2.** For a tripartite mixed state  $\rho_{ABC}$  of  $2 \otimes 2 \otimes 4$  systems, the squared entanglement of formation obeys the monogamy relation

$$E_f^2(\rho_{A|BC}) - E_f^2(\rho_{AB}) - E_f^2(\rho_{AC}) \geq 0, \quad (15)$$

where  $\rho_{AB}$  and  $\rho_{AC}$  are the reduced quantum states of  $2 \otimes 2$  and  $2 \otimes 4$  subsystems, respectively.

*Proof.* We first analyze the pure state case. In a tripartite pure state  $|\psi_{ABC}\rangle$  of the  $2 \otimes 2 \otimes 4$  systems, we can derive

$$\begin{aligned} &E_f^2(|\psi_{A|BC}\rangle) - E_f^2(\rho_{AB}) - E_f^2(\rho_{AC}) \\ &= E_f^2[C^2(|\psi_{A|BC}\rangle)] - E_f^2[C^2(\rho_{AB})] - E_f^2[C^2(\rho_{AC})] \\ &\geq E_f^2(C_{AB}^2 + C_{AC}^2) - E_f^2(C_{AB}^2) - E_f^2(C_{AC}^2) \\ &\geq 0, \end{aligned} \quad (16)$$

where we have used the property  $E_f(\rho_{AC}) = E_f[C^2(\rho_{AC})]$  as proved in Theorem 1 and the property of  $|\psi_{ABC}\rangle$  being equivalent to a two-qubit state under the partition  $A|BC$  in the first equality, the monotonic property of  $E_f^2(C^2)$  and the monogamy relation  $C_{A|BC}^2 \geq C_{AB}^2 + C_{AC}^2$  [7] in the second inequality, and the convexity of function  $E_f^2(C^2)$  [32] in the last inequality. Thus, we have proven the monogamy relation for pure state cases. Next, we prove it for mixed states. The EOF in bipartite partition  $A|BC$  is  $E_f(\rho_{A|BC}) = \min \sum_i p_i E_f(|\psi_{A|BC}^i\rangle)$  with the minimum running over all pure-state decompositions. Under the optimal decomposition  $\{p_i, |\psi_{ABC}^i\rangle\}$ , we can get

$$\begin{aligned} E_f(\rho_{A|BC}) &= \sum_i p_i E_f(|\psi_{A|BC}^i\rangle) = \sum_i E1_i \\ E_f'(\rho_{AJ}) &= \sum_i p_i E_f(\rho_{AJ}^i) = \sum_i E_j i, \end{aligned} \quad (17)$$

where  $E_f'(\rho_{AJ})$  (with  $J = B, C$  and  $j = 2, 3$ ) is the average EOF under the specific decomposition. Consequently, we can derive

$$\begin{aligned} &E_f^2(\rho_{A|BC}) - E_f'^2(\rho_{AB}) - E_f'^2(\rho_{AC}) \\ &= (\sum_i E1_i)^2 - (\sum_i E2_i)^2 - (\sum_i E3_i)^2 \\ &= \sum_i (E1_i^2 - E2_i^2 - E3_i^2) + \Delta \geq 0, \end{aligned} \quad (18)$$

where, in the second equation, the first term is nonnegative due to the proved monogamy relation in the pure state case, and the second term  $\Delta = 2 \sum_i \sum_{k=i+1} (E1_i E1_k - \sum_j E_j i E_j k)$  is also nonnegative from a rigorous analysis given in Appendix C. On the other hand, we have

$$E_f(\rho_{AB}) \leq E_f'(\rho_{AB}), E_f(\rho_{AC}) \leq E_f'(\rho_{AC}) \quad (19)$$

since  $E_f'$  is a specific average EOF which is not less than that under the optimal pure state decomposition. Combining Eqs. (18) and (19), we obtain the monogamy relation for mixed states, which completes the proof of this theorem.

**Theorem 3.** For an arbitrary tripartite quantum state  $\rho_{ABC}$  of  $2 \otimes 2 \otimes 2^{N-2}$  systems, the monogamy relation  $E_f^2(\rho_{A|BC}) - E_f^2(\rho_{AB}) - E_f^2(\rho_{AC}) \geq 0$  is satisfied.

*Proof.* In a tripartite pure state  $|\psi_{ABC}\rangle$  of  $2 \otimes 2 \otimes 2^{N-2}$  systems, the party  $C$  is equivalent to a logic four-level subsystem according to the Schmidt decomposition [51] in the partition  $AB|C$ . Therefore, the pure state monogamy relation for this theorem is automatically satisfied in terms of the result of Theorem 2. Also, we can prove it for the mixed state case. For the mixed state  $\rho_{ABC}$ , we have  $E_f(\rho_{A|BC}) = \min \sum_i p_i E_f(|\psi_{A|BC}^i\rangle)$ , with the minimum running over all the pure state decompositions. Under the optimal decomposition  $\{p_i, |\psi_{ABC}^i\rangle\}$ , we can obtain  $E_f(\rho_{A|BC}) = \sum_i p_i E_f(|\psi_{A|BC}^i\rangle) = \sum_i E1_i$ ,  $E_f'(\rho_{AB}) = \sum_i p_i E_f(\rho_{AB}^i) = \sum_i E2_i$ , and  $E_f'(\rho_{AC}) = \sum_i p_i E_f(\rho_{AC}^i) = \sum_i E3_i$ , in which  $E_f'(\rho_{AB})$  and  $E_f'(\rho_{AC})$

are the average entanglement in the specific decomposition. We thus have

$$\begin{aligned} & E_f^2(\rho_{A|BC}) - E_f'^2(\rho_{AB}) - E_f'^2(\rho_{AC}) \\ &= \sum_i p_i^2 [E_f^2(|\psi_{A|BC}^i\rangle) - E_f^2(\rho_{AB}^i) - E_f^2(\rho_{AC}^i)] \\ &+ 2 \sum_i \sum_{k=i+1}^3 (E_{1i} E_{1k} - \sum_{j=2}^3 E_{ji} E_{jk}), \end{aligned} \quad (20)$$

where the first term is nonnegative since the monogamy relation is satisfied for the pure-state case, and the second term is nonnegative as well, as shown in Appendix C. Moreover, we have  $E_f'(\rho_{AB}) \geq E_f(\rho_{AB})$  and  $E_f'(\rho_{AC}) \geq E_f(\rho_{AC})$  because  $E_f'$  is the average EOF under a specific decomposition. Therefore, we have

$$E_f^2(\rho_{A|BC}) - E_f^2(\rho_{AB}) - E_f^2(\rho_{AC}) \geq 0. \quad (21)$$

At this stage, we prove the hierarchical  $k$ -partite monogamy relations of SEF in an  $N$ -qubit mixed state  $\rho_{A_1 A_2 \dots A_N}$ . According to Theorem 3, the three-partite monogamy relation in the  $N$ -qubit system is satisfied, and we have

$$E_f^2(\rho_{A_1|A_2 \dots A_N}) \geq E_f^2(\rho_{A_1 A_2}) + E_f^2(\rho_{A_1|A_3 \dots A_N}). \quad (22)$$

Applying theorem 3 to the subsystem  $\rho_{A_1|A_3 \dots A_N}$  again, we can derive the four-partite monogamy relation  $E_f^2(\rho_{A_1|A_2 \dots A_N}) \geq E_f^2(\rho_{A_1 A_2}) + E_f^2(\rho_{A_1 A_3}) + E_f^2(\rho_{A_1|A_4 \dots A_N})$ . By the successive application of the Theorem 3, we can obtain a set of hierarchical  $k$ -partite monogamy relations for SEF with  $k \in \{3, 4, \dots, N\}$ , such that we complete the whole proof for the monogamy inequalities shown in Eq. (5).

### III. HIERARCHICAL INDICATORS FOR MULTIPARTITE ENTANGLEMENT

For an  $N$ -qubit pure state  $|\psi_N\rangle$ , we are able to construct a set of hierarchical multipartite entanglement indicators based on the corresponding monogamy relations for the SEF

$$\begin{aligned} \tau_{SEF(k)}(|\psi_N\rangle) &= E_f^2(|\psi\rangle_{A_1|A_2 \dots A_N}) - \sum_{i=2}^{k-1} E_f^2(\rho_{A_1 A_i}) \\ &\quad - E_f^2(\rho_{A_1|A_k \dots A_N}), \end{aligned} \quad (23)$$

which can be used to detect multipartite entanglement for the  $k$ -partite case of an  $N$ -qubit system under the partition  $A_1|A_2 \dots A_N$ . Moreover, for  $N$ -qubit mixed states, we can construct two types of multipartite entanglement indicators

$$\begin{aligned} \tau_{SEF(k)}^{(1)}(\rho_N) &= \min \sum_i p_i \tau_{SEF(k)}(|\psi_N^i\rangle), \\ \tau_{SEF(k)}^{(2)}(\rho_N) &= E_f^2(\rho_{A_1|A_2 \dots A_N}) - \sum_{i=2}^{k-1} E_f^2(\rho_{A_1 A_i}) \\ &\quad - E_f^2(\rho_{A_1|A_k \dots A_N}), \end{aligned} \quad (24)$$

FIG. 1: (Color online) The multipartite entanglement indicator  $\tau_{SEF(k)}(|W_{20}\rangle)$  as a function of party number  $k$ , where the nonzero values indicate the existence of multipartite entanglement in the  $k$ -partite case of a 20-qubit  $W$  state with  $k \in [3, 20]$ .

where the first type is based on the convex roof extension with the minimum running over all the pure-state decompositions  $\{p_i, |\psi_N^i\rangle\}$ , while the second type comes from the mixed-state monogamy relations for SEF. When the party number  $k = N$ , the two indicators in Eq. (24) are just the multiqubit entanglement indicators introduced in Ref. [32], which can detect entangled multiqubit states without the concurrence and  $n$ -tangles [52, 53]. The detection ability of the first type of indicator is stronger than that of the second one, but the computability of the second type is better since the bipartite multiqubit EOF can be obtained via quantum discord.

As an application, we first analyze the  $N$ -qubit  $W$  state which has the form

$$|W_N\rangle = \frac{1}{\sqrt{N}}(|10 \dots 0\rangle + |01 \dots 0\rangle + \dots + |00 \dots 1\rangle). \quad (25)$$

For this quantum state, the  $k$ -partite  $N$ -qubit monogamy relations of SC as shown in Eq. (2) are saturated, and thus, the concurrence-based multipartite entanglement detection does not work. However, we can use the newly introduced SEF-based indicator to represent the multipartite entanglement in the  $k$ -partite case of  $N$ -qubit systems. After some deduction, we have

$$\begin{aligned} \tau_{SEF(k)}(|W_N\rangle) &= E_f^2(C_{A_1|A_2 \dots A_N}^2) - (k-2)E_f^2(C_{A_1 A_2}^2) \\ &\quad - E_f^2(C_{A_1|A_k \dots A_N}^2), \end{aligned} \quad (26)$$

where we have used the symmetry of qubit permutations in the  $W$  state and the squared concurrences are  $C_{A_1|A_2 \dots A_N}^2 = 4(N-1)/N^2$ ,  $C_{A_1 A_2}^2 = 4/N^2$ , and  $C_{A_1|A_k \dots A_N}^2 = 4(N-k+1)/N^2$ , respectively. This set of  $\tau_{SEF(k)}$  is positive since the SEF is a convex function of SC and all the SCs in Eq. (26) are nonzero [32]. The nonzero  $\tau_{SEF(k)}$  indicates the existence of multipartite entanglement in the  $k$ -partite case of the  $W$  state. In Fig 1, we plot the indicator as a function of party number  $k$  in a 20-qubit  $W$  state, where the nonzero value detects the multipartite entanglement in the  $k$ -partite case. Moreover, the hierarchy relations are embodied by the monotonically increasing values of the indicator, with the minimum  $\tau_{SEF(3)} = 0.00603$  and the maximum  $\tau_{SEF(20)} = 0.06989$ , respectively.

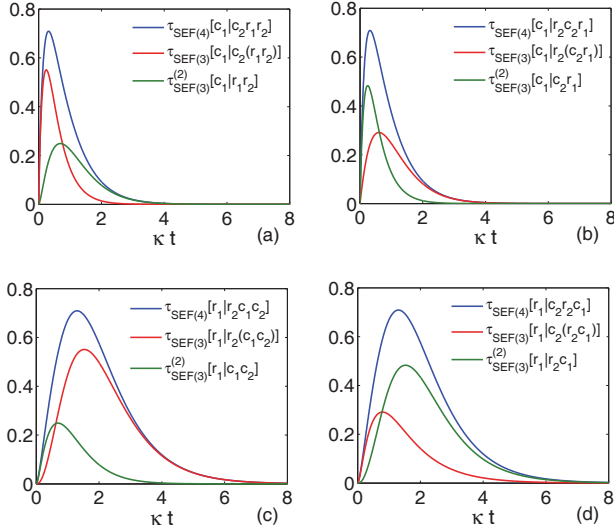

FIG. 2: (Color online) The hierarchical multipartite entanglement indicators as functions of the time evolution parameter  $\kappa t$  in different partitions of composite cavity-reservoir systems: (a)  $c_1|c_2r_1r_2$ , (b)  $c_1|r_2c_2r_1$ , (c)  $r_1|r_2c_1c_2$ , and (d)  $r_1|c_2r_2c_1$ .

Next, we make use of the hierarchical multipartite entanglement indicators to analyze a practical dynamical procedure of two composite cavity-reservoir systems. The interaction of a single cavity-reservoir system is described by the Hamiltonian [54–57]  $\hat{H} = \hbar\omega\hat{a}^\dagger\hat{a} + \hbar\sum_{k=1}^N\omega_k\hat{b}_k^\dagger\hat{b}_k + \hbar\sum_{k=1}^N g_k(\hat{a}\hat{b}_k^\dagger + \hat{b}_k\hat{a}^\dagger)$ . When the initial state is  $|\Phi_0\rangle = (\alpha|00\rangle + \beta|11\rangle)_{c_1c_2}|00\rangle_{r_1r_2}$ , with the dissipative reservoirs being in the vacuum state, the output state is equivalent to a four-qubit state and has the form [54]

$$|\Phi_t\rangle = \alpha|0000\rangle_{c_1r_1c_2r_2} + \beta|\phi_t\rangle_{c_1r_1}|\phi_t\rangle_{c_2r_2}, \quad (27)$$

where  $|\phi_t\rangle = \xi(t)|10\rangle + \chi(t)|01\rangle$ , with the amplitudes being  $\xi(t) = \exp(-\kappa t/2)$  and  $\chi(t) = [1 - \exp(-\kappa t)]^{1/2}$ . Under the partition  $c_1|c_2r_1r_2$ , the hierarchical multipartite entanglement indicators obey the following relation:

$$\tau_{SEF(4)}(|\Phi_t\rangle_{c_1|c_2r_1r_2}) = \tau_{SEF(3)}(|\Phi_t\rangle_{c_1|c_2(r_1r_2)}) + \tau_{SEF(3)}^{(2)}(\rho_{c_1|r_1r_2}), \quad (28)$$

where  $\tau_{SEF(3)}$  and  $\tau_{SEF(4)}$  are the multipartite entanglement indicators for the three-partite and four-partite cases of the output state, and  $\tau_{SEF(3)}^{(2)}$  detects the tripartite entanglement in the three-qubit mixed state. In Fig. 2(a), we plot this set of hierarchical indicators as functions of the time evolution  $\kappa t$  (the initial-state parameter is chosen to be  $\alpha = 1/\sqrt{3}$ ), where the nonzero values indicate the existence of multipartite entanglement. Similarly, for the partitions  $c_1|r_2c_2r_1$ ,  $r_1|r_2c_1c_2$ , and  $r_1|c_2r_2c_1$ , we can also utilize the corresponding hierarchical SEF-based indicators to detect the multipartite entanglement in pure and mixed states of the composite cavity-reservoir systems, which are plotted in Fig. 2(b)-2(d). Here, it should be pointed out that the advantage of SEF-based indicators is that the multiqubit EOF of mixed states can be obtained via

an effective method for calculating quantum discord [47] (the details of the calculation are presented in Appendix D). However, for the concurrence-based indicators, their calculation is very difficult because the bipartite multiqubit concurrence in mixed states needs to resort to the convex-roof extension.

The hierarchy property of multipartite entanglement indicators  $\tau_{SEF(k)}$  lies in not only the values of different indicators but also the enhanced detection ability along with the party number  $k$ . In Ref. [32], it was proved that the nonzero indicator value of  $N$ -partite  $N$ -qubit quantum states is a necessary and sufficient condition for the existence of multiqubit entanglement. However, when one of the parties contains two or more qubits, the nonzero value of the indicator is only a sufficient condition for multipartite entanglement detection, which is because there exist multipartite entangled states with zero indicator values. As an example, we consider the tripartite case of a four-qubit quantum state in  $2 \otimes 2 \otimes 4$  systems,

$$|\psi\rangle_{A_1A_2(A_3A_4)} = \frac{1}{2}(|00\bar{0}\rangle + |10\bar{1}\rangle + |01\bar{2}\rangle - |11\bar{3}\rangle), \quad (29)$$

where the third party has two qubits  $A_3$  and  $A_4$  with the bases  $|\bar{0}\rangle = |00\rangle$ ,  $|\bar{1}\rangle = |01\rangle$ ,  $|\bar{2}\rangle = |10\rangle$ , and  $|\bar{3}\rangle = |11\rangle$ , respectively. This quantum state is multipartite entangled since the EOF is nonzero in any bipartite partition of the tripartite system  $A_1A_2(A_3A_4)$ . But the tripartite entanglement indicator is  $\tau_{SEF(3)}(|\psi\rangle_{A_1A_2(A_3A_4)}) = 0$ , which fails to detect the multipartite entanglement [here, the EOF of reduced quantum state  $\rho_{A_1(A_3A_4)}$  is  $E_f(A_1|A_3A_4) = 1$ , since it is the maximal entangled mixed state in  $2 \otimes 4$  systems [58, 59]]. On the other hand, when the quantum state in Eq. (29) is taken to be a four-party case of a  $2 \otimes 2 \otimes 2 \otimes 2$  system, it has the form

$$|\psi\rangle_{A_1A_2A_3A_4} = \frac{1}{2}(|0000\rangle + |1001\rangle + |0110\rangle - |1111\rangle). \quad (30)$$

In this case, we can derive  $\tau_{SEF(4)}(|\psi\rangle) = 1$ , which indicates the existence of genuine multipartite entanglement. In fact, this quantum state is just the four-qubit cluster state which is genuinely four-partite entangled [60, 61].

#### IV. DISCUSSION

Until now, the quantitative relation between the EOF and SC in general bipartite systems has been an open problem. However, Theorem 1 in this paper provides an analytical expression for the relation of EOF and SC in  $2 \otimes d$  systems, leading to the mixed-state concurrence in  $2 \otimes d$  systems being available as long as we get the corresponding EOF. This is an important step forward in calculating the mixed-state concurrence since the mixed-state EOF beyond two-qubit cases can be derived via effective methods for calculating quantum discord [40–49]. For example, in the dynamical evolution of multipartite cavity-reservoir systems analyzed in Sec. III, the calculation of SC  $C_{c_1|r_1r_2}^2$  is extremely difficult according to the convex-roof extension. But we can deduce this concurrence via the corresponding EOF. Based on the Koashi-Winter formula [19] and the quantum discord in subsystem  $c_1c_2$ , we

FIG. 3: (Color online) Entanglement dynamics of squared concurrences as a functions of time evolution  $\kappa t$  and the initial amplitude  $\alpha$ : (a) squared concurrence  $C^2(\rho_{c_1|r_1r_2})$  and (b) entanglement monogamy  $C^2(\rho_{c_1|r_1r_2}) - C^2(\rho_{c_1r_1}) - C^2(\rho_{c_1r_2})$ .

have the EOF (see details in Appendix D)

$$E_f(\rho_{c_1|r_1r_2}) = -\eta_1 \log_2 \eta_1 - (1 - \eta_1) \log_2 (1 - \eta_1), \quad (31)$$

where the parameter is  $\eta_1 = [1 - (1 - 4\beta^2\xi^2\chi^2)^{1/2}]/2$ . According to Theorem 1 in Sec. II, we have the relation

$$E_f(\rho_{c_1|r_1r_2}) = h \left( \frac{1 + \sqrt{1 - C_{c_1|r_1r_2}^2}}{2} \right), \quad (32)$$

where  $h(x) = -x \log_2 x - (1 - x) \log_2 (1 - x)$  is the binary entropy. Combining Eqs. (31) and (32), we can derive the SC

$$C_{c_1|r_1r_2}^2 = 4\beta^2\xi^2\chi^2, \quad (33)$$

where  $\beta$  is the initial amplitude and the time evolution parameters are  $\xi = \exp(-\kappa t/2)$  and  $\chi = [1 - \exp(-\kappa t)]^{1/2}$ , respectively. In Fig. 3(a), we plot the concurrence  $C_{c_1|r_1r_2}^2$  as a function of time evolution  $\kappa t$  and the initial amplitude  $\alpha$ , which characterizes the evolution of SC in the dynamical procedure. Furthermore, in Fig. 3(b), the entanglement distribution  $C^2(\rho_{c_1|r_1r_2}) - C^2(\rho_{c_1r_1}) - C^2(\rho_{c_1r_2})$  is plotted, which verifies the monogamy property of SC in the three-qubit mixed state.

It was proven in Ref. [32] that the SEF is monogamous in the  $N$ -partite case, as shown in Eq. (1) where each party contains one qubit. In this paper, we further prove that the SEF monogamy is satisfied even when the last party contains two or more qubits, and thus, we obtain a set of hierarchical  $k$ -partite monogamy relations,

$$\begin{aligned} & E_f^2(\rho_{A_1|A_2 \dots A_N}) \\ & \geq E_f^2(\rho_{A_1|A_2}) + E_f^2(\rho_{A_1|A_3 \dots A_N}) \\ & \geq E_f^2(\rho_{A_1|A_2}) + E_f^2(\rho_{A_1|A_3}) + E_f^2(\rho_{A_1|A_4 \dots A_N}) \\ & \vdots \\ & \geq E_f^2(\rho_{A_1|A_2}) + \dots + E_f^2(\rho_{A_1|A_{N-2}}) + E_f^2(\rho_{A_1|A_{N-1}A_N}) \\ & \geq E_f^2(\rho_{A_1|A_2}) + \dots + E_f^2(\rho_{A_1|A_{N-1}}) + E_f^2(\rho_{A_1|A_N}), \end{aligned} \quad (34)$$

where the specific monogamy relation for  $k = N$  reproduces the important result recently revealed in Ref. [32]. Note that

the monogamy score is increasing along with the party number  $k$  due to the hierarchy property of the inequalities, and on the basis of the hierarchy property we correspondingly present a set of multipartite entanglement indicators. For a general  $N$ -qubit mixed state  $\rho_N$ , the detection ability of the multipartite entanglement indicator  $\tau_{SEF(k)}$  is also enhanced along with the increasing of party number  $k$ . When  $k < N$ , the nonzero value of the indicator is only a sufficient condition for the existence of multipartite entanglement, but when  $k = N$ , the nonzero value is both necessary and sufficient.

As shown in Eqs. (2) and (5), both SC and SEF satisfy the monogamy relation in multipartite  $2 \otimes 2 \otimes 2 \dots \otimes 2 \otimes d$  systems. However, it is still an open question whether or not the monogamy properties of SC and SEF are equivalent in multipartite systems of arbitrary dimension. Furthermore, does the SEF possess a *better* monogamy property than the SC?

First, we analyze multipartite  $2 \otimes d_2 \otimes d_3 \dots \otimes d_{N-1} \otimes d_N$  systems, where only the first party is a two-level subsystem and the other parties are multilevel subsystems. In this case, we have the following theorem, and the proof can be seen in Appendix E.

**Theorem 4.** For multipartite  $2 \otimes d_2 \otimes d_3 \dots \otimes d_{N-1} \otimes d_N$  systems, the monogamy property of squared entanglement of formation is superior to that of squared concurrence.

Here, it should be noted that the general monogamy property of SC is still an open problem for  $2 \otimes d_2 \otimes d_3 \dots \otimes d_{N-1} \otimes d_N$  systems. However, according to the Theorem 4, we know that the SEF in the multipartite systems should be monogamous whenever the SC possesses this property, and furthermore, the SEF may still be monogamous even if the SC were polygamous. As an example, we consider a four-partite mixed state  $\rho_{A_1\tilde{A}_2\tilde{A}_3\tilde{A}_4}$  of  $2 \otimes d_2 \otimes d_3 \otimes d_4$  systems. Suppose that the bipartite squared concurrences are  $C_{A_1|\tilde{A}_2\tilde{A}_3\tilde{A}_4}^2 = 0.7$ , and  $C_{A_1\tilde{A}_2}^2 = C_{A_1\tilde{A}_3}^2 = C_{A_1\tilde{A}_4}^2 = 0.3$ . Then we find that the SC is polygamous in this quantum state, *i.e.*,

$$C_{A_1|\tilde{A}_2\tilde{A}_3\tilde{A}_4}^2 - \sum_{i=2}^4 C_{A_1\tilde{A}_i}^2 = -0.2. \quad (35)$$

However, if we use the SEF to characterize the entanglement distribution in this quantum state, we can derive

$$\begin{aligned} & E_f^2(\rho_{A_1|\tilde{A}_2\tilde{A}_3\tilde{A}_4}) - \sum_{i=2}^4 E_f^2(\rho_{A_1\tilde{A}_i}) \\ & = E_f^2(C_{A_1|\tilde{A}_2\tilde{A}_3\tilde{A}_4}^2) - \sum_{i=2}^4 E_f^2(C_{A_1\tilde{A}_i}^2) \\ & = 0.594779 - 3 \times 0.166494 \\ & = 0.0952982, \end{aligned} \quad (36)$$

which is monogamous.

Next, we investigate the monogamy properties of SEF and SC for multipartite quantum systems where the first party is a multilevel subsystem. In Ref. [62], Ou indicated that the SC is not monogamous for multipartite higher-dimensional systems, with a counterexample of  $3 \otimes 3 \otimes 3$  systems being given

FIG. 4: (Color online) The different distribution properties of  $M(SEF) = E_f^2(A|BC) - E_f^2(AB) - E_f^2(AC)$  and  $M(SC) = C^2(A|BC) - C^2(AB) - C^2(AC)$  as functions of parameter  $\theta$  in  $4 \otimes 2 \otimes 2$  systems, where the SEF is monogamous and the SC is polygamous.

by [62]

$$|\Psi\rangle_{ABC} = \frac{1}{\sqrt{6}}(|123\rangle - |132\rangle + |231\rangle - |213\rangle + |312\rangle - |321\rangle), \quad (37)$$

in which the monogamy score is  $C_{A|BC}^2 - C_{AB}^2 - C_{AC}^2 = -2/3$ . However, when we use SEF to characterize the entanglement distribution in this quantum state, we find that the corresponding monogamy score is

$$\begin{aligned} E_f^2(|\Psi\rangle_{A|BC}) - E_f^2(\rho_{AB}) - E_f^2(\rho_{AC}) \\ = (\log_2 3)^2 - 1 - 1 \\ \simeq 0.51211, \end{aligned} \quad (38)$$

which is monogamous and indicates genuine tripartite entanglement. Therefore, the monogamy properties of SEF and SC are inequivalent in multilevel systems. Moreover, even when only the first party is multilevel, the monogamy properties of SEF and SC are still different. As an example, we analyze a tripartite pure state of  $4 \otimes 2 \otimes 2$  systems

$$|\Phi\rangle_{ABC} = \frac{1}{\sqrt{2}}(\alpha|000\rangle + \beta|110\rangle + \alpha|201\rangle + \beta|311\rangle), \quad (39)$$

where the parameters are  $\alpha = \cos\theta$  and  $\beta = \sin\theta$ . In Fig. 4, we plot the monogamy properties of SEF and SC as functions of parameter  $\theta$ , and it can be seen that the SEF is monogamous whereas the SC is polygamous (the details of the analysis of the entanglement distribution property are given in Appendix F).

It is worth pointing out that a profound understanding of the monogamy property of SEF for a general multipartite system is still lacking. From the above analysis on multi-level systems, we may make the following two conjectures.

**Conjecture 1.** For multipartite  $2 \otimes d_2 \otimes d_3 \cdots \otimes d_{N-1} \otimes d_N$  systems, the squared entanglement of formation may be monogamous.

**Conjecture 2.** For multipartite arbitrary  $d$ -dimensional quantum systems, the squared entanglement of formation may be monogamous.

The proofs of these two conjectures are highly challenging and may demand some exotic tools for characterizing the EOF in bipartite higher-dimensional systems, which is currently being explored in the quantum information community.

## V. CONCLUSIONS

To conclude, we have proven exactly that when an  $N$ -qubit quantum system is divided into  $k$  parties, SEF obeys a set of hierarchical  $k$ -partite monogamy relations, as shown in Eq. (5), which is an important generalization of the former  $N$ -partite  $N$ -qubit result [32]. In comparison with the similar hierarchical monogamy properties of SC [7], the merits of the SEF case lie in its computability via quantum discord and its capability of multipartite entanglement detection. Based on this set of monogamy relations for SEF, we are able to construct multipartite entanglement indicators for various  $k$ -partite cases, which have a hierarchy structure and are still workable even when concurrence-based indicators lose their efficacy. In the evolution of four-partite cavity-reservoir systems, the introduced indicators are utilized to analyze the dynamics of multipartite entanglement, where a quantitative hierarchical relation between tripartite and four-partite entanglement indicators is given in Eq. (28). Moreover, the hierarchy property of multipartite entanglement indicators also lies in the improved detection ability along with the increasing of party number  $k$ .

As an important by-product, we have also derived the analytical relation between EOF and SC in an arbitrary mixed state of  $2 \otimes d$  systems (Theorem 1). This leads to the  $2 \otimes d$  concurrence being computable without resorting to the convex-roof extension [39] since the EOF is available via effective methods for calculating quantum discord [40–49]. Therefore, beyond two-qubit cases, the quantitative characterization of the monogamy relation of SC is possible. As an example, we have calculated the entanglement distribution of SC in cavity-reservoir systems, which is plotted in Fig. 3.

Finally, we have made a comparative study of the monogamy properties of SEF and SC in multilevel systems. For multipartite  $2 \otimes d_2 \otimes d_3 \cdots \otimes d_{N-1} \otimes d_N$  systems, we have proven that the monogamy property of SEF is superior to that of SC. When the first subsystem is not a qubit, the concrete examples illustrate that the SEF can be monogamous even if the SC is polygamous. However, in a general multipartite system, the monogamy property of SEF is still an open problem, and proofs for the two conjectures are still needed.

#### Appendix A: Proof for the negativity of the second-order derivative in equation (7)

In Eq. (7) of the main text, the second-order derivative has the form

$$\frac{d^2 E_f}{dx^2} = g(x) \cdot \{-2\sqrt{1-x} + x \cdot \ln(\frac{1+\sqrt{1-x}}{1-\sqrt{1-x}})\}, \quad (\text{A1})$$

where  $x = C^2$  and the factor  $g(x) = 1/[2 \cdot (\ln 16) \cdot x(1-x)^{3/2}]$ . Now we prove that the derivative is negative.

In the region  $x \in (0, 1)$ , the factor  $g(x)$  is positive, and then the negativity of the derivative is equivalent to  $M(x) < 0$ , with

$$M(x) = -2\sqrt{1-x} + x \cdot \ln(\frac{1+\sqrt{1-x}}{1-\sqrt{1-x}}). \quad (\text{A2})$$

In order to determine the sign of  $M(x)$ , we first analyze the monotonic property of this function. After some deduction, we find that the first-order derivative of  $M(x)$  is

$$\frac{dM(x)}{dx} = \ln(\frac{1+\sqrt{1-x}}{1-\sqrt{1-x}}), \quad (\text{A3})$$

which is positive since the term in the logarithm is larger than 1. Therefore, the function  $M(x)$  is monotonically increasing in the region  $x \in (0, 1)$ . Next we analyze the values of  $M(x)$  at two end points. When  $x = 0$ , we can get

$$\begin{aligned} \lim_{x \rightarrow +0} M(x) &= \lim_{x \rightarrow +0} \{-2\sqrt{1-x} + x \cdot \ln(\frac{1+\sqrt{1-x}}{1-\sqrt{1-x}})\} \\ &= \lim_{x \rightarrow +0} -2\sqrt{1-x} + \lim_{x \rightarrow +0} \frac{\ln(\frac{1+\sqrt{1-x}}{1-\sqrt{1-x}})}{\frac{1}{x}} \\ &= -2 + \lim_{x \rightarrow +0} \frac{x}{\sqrt{1-x}} \\ &= -2, \end{aligned} \quad (\text{A4})$$

where we have used L'Hospital's rule in the third equation. When  $x = 1$ , it is easy to obtain  $M(1) = 0$ . Combining the two end-point values with the monotonic property of  $M(x)$ , we have  $M(x) < 0$  in the region  $x \in (0, 1)$ , and thus, the second-order derivative  $d^2 E_f/dx^2 < 0$  in the same region.

Furthermore, we analyze the second-order derivative at the end points. When  $x = 0$ , we get

$$\begin{aligned} \lim_{x \rightarrow +0} \frac{d^2 E_f}{dx^2} &= \lim_{x \rightarrow +0} g(x) \cdot M(x) \\ &= \lim_{x \rightarrow +0} g(x) \cdot \lim_{x \rightarrow +0} M(x) \\ &= \infty \cdot (-2) \\ &= -\infty, \end{aligned} \quad (\text{A5})$$

FIG. 5: (Color online) The second-order derivative  $d^2 E_f/dx^2$  is plotted as a function of  $x$ , with  $x = C^2$ , which is negative, and as a result, the EOF is a concave function of SC.

where the result of Eq. (A4) has been used in the third equality. On the other hand, when  $x = 1$ , we can derive

$$\begin{aligned} \lim_{x \rightarrow 1} \frac{d^2 E_f}{dx^2} &= \lim_{x \rightarrow 1} \frac{M(x)}{g(x)} \\ &= \lim_{x \rightarrow 1} \frac{\ln[(1+\sqrt{1-x})/(1-\sqrt{1-x})]}{(\ln 16) \cdot (2-5x)\sqrt{1-x}} \\ &= \lim_{x \rightarrow 1} \frac{-1/(x\sqrt{1-x})}{[3 \cdot (\ln 16) \cdot (5x-4)]/[2\sqrt{1-x}]} \\ &= \frac{-2}{3 \cdot \ln 16} \\ &\approx -0.24. \end{aligned} \quad (\text{A6})$$

Thus, we prove that the second-order derivative  $d^2 E_f/dx^2$  is negative in the whole region  $x \in [0, 1]$  and complete the proof of Eq. (7) in the main text. In Fig. 5, we plot the second-order derivative as a function of  $x$ , which illustrates our analytical result.

#### Appendix B: Proof for the positivity of the second-order derivative in equation (9)

In Eq. (9) of the main text, the second-order derivative has the form

$$\frac{d^2 E_f}{dC^2} = u(C) \cdot \{-2\sqrt{1-C^2} + \ln(\frac{1+\sqrt{1-C^2}}{1-\sqrt{1-C^2}})\}, \quad (\text{B1})$$

where the factor is  $u(C) = 1/[(\ln 4) \cdot (1-C^2)^{3/2}]$ . Now we prove that the derivative is positive.

In the region  $C \in (0, 1)$ , the factor  $u(C)$  is positive and then the positivity of the derivative is equivalent to  $Q(C) > 0$ , with

$$Q(C) = -2\sqrt{1-C^2} + \ln(\frac{1+\sqrt{1-C^2}}{1-\sqrt{1-C^2}}). \quad (\text{B2})$$

FIG. 6: (Color online) The second-order derivative  $d^2 E_f / dC^2$  is plotted as a function of  $C$ , which is positive, and as a result, the EOF is a convex function of concurrence  $C$ .

In order to determine the sign of  $Q(C)$ , we first analyze the monotonic property of this function. After some deduction, we find the first-order derivative of  $Q(C)$  is

$$\frac{dQ(C)}{dC} = \frac{-2\sqrt{1-C^2}}{C}, \quad (\text{B3})$$

which is negative since the concurrence  $C$  ranges in  $(0, 1)$ . Therefore, the function  $Q(C)$  is monotonically decreasing in the region  $C \in (0, 1)$ . Next, we investigate the values of  $Q(C)$  at two end points, which can be written as

$$\begin{aligned} \lim_{C \rightarrow +0} Q(C) &= +\infty \\ \lim_{C \rightarrow 1} Q(C) &= 0. \end{aligned} \quad (\text{B4})$$

Combining Eq. (B4) with the monotonic property of  $Q(C)$ , we find that the function  $Q(C)$  is positive in the region  $C \in (0, 1)$ , and thus the second-order derivative  $d^2 E_f / dC^2 > 0$  in the same region.

Furthermore, we analyze the second-order derivative at the endpoints. When  $C = 0$ , we have

$$\lim_{C \rightarrow +0} \frac{d^2 E_f}{dC^2} = \lim_{C \rightarrow +0} u(C) \cdot Q(C) = +\infty. \quad (\text{B5})$$

On the other hand, when  $C = 1$ , we can derive

$$\begin{aligned} \lim_{C \rightarrow 1} \frac{d^2 E_f}{dC^2} &= \lim_{C \rightarrow 1} u(C) \cdot Q(C) \\ &= \lim_{C \rightarrow 1} \frac{-2\sqrt{1-C^2} + \ln\left(\frac{1+\sqrt{1-C^2}}{1-\sqrt{1-C^2}}\right)}{(1-C^2)^{3/2} \cdot \ln 4} \\ &= \lim_{C \rightarrow 1} \frac{1}{\ln 4} \cdot \frac{\frac{-2\sqrt{1-C^2}}{C}}{-3C \cdot \sqrt{1-C^2}} \\ &= \frac{2}{3 \cdot \ln 4} \\ &\approx 0.48. \end{aligned} \quad (\text{B6})$$

Thus, we prove that the second-order derivative  $d^2 E_f / dC^2 > 0$  in the whole region  $C \in [0, 1]$  and then complete the proof

of Eq. (9) in the main text. In Fig.6, we plot the derivative as a function of concurrence  $C$ , which verifies our analytical result.

### Appendix C: Nonnegative second terms in equation (18) and (20)

We first analyze the term in Eq. (18) of the main text, which has the form

$$\Delta = 2 \sum_i \sum_{k=i+1}^3 (E1_i E1_k - \sum_{j=2}^3 E j_i E j_k). \quad (\text{C1})$$

For two arbitrary pure state components  $|\psi_i\rangle$  and  $|\psi_k\rangle$  in the optimal pure state decomposition, we can obtain

$$\begin{aligned} E1_i^2 E1_k^2 &\geq (E2_i^2 + E3_i^2) \cdot (E2_k^2 + E3_k^2) \\ &= (E2_i E2_k)^2 + (E3_i E3_k)^2 + (E2_i E3_k)^2 \\ &\quad + (E3_i E2_k)^2 \\ &\geq (E2_i E2_k)^2 + (E3_i E3_k)^2 + 2(E2_i E2_k) \\ &\quad \times (E3_i E3_k) \\ &= \left( \sum_{j=2}^3 E j_i E j_k \right)^2, \end{aligned} \quad (\text{C2})$$

where we have used the monogamy relation for the pure-state case in the first inequality and the perfect square trinomial equation in the second inequality. After taking the square root on both sides of Eq. (C2), we can get

$$E1_i E1_k - \sum_{j=2}^3 E j_i E j_k \geq 0. \quad (\text{C3})$$

Since  $|\psi_i\rangle$  and  $|\psi_k\rangle$  are two arbitrary components, the inequality in Eq. (C3) is also satisfied for any other components, and thus the second term  $\Delta \geq 0$  in Eq. (18).

In Eq. (20) of the main text, the second term has the same form as that in Eq. (18). Under the optimal pure-state decomposition for  $E_f(\rho_{A|BC})$ , we choose two arbitrary pure-state components  $|\psi_{ABC}^i\rangle$  and  $|\psi_{ABC}^k\rangle$ . After a derivation similar to those of Eqs. (C2) and (C3), we get  $E1_i E1_k - \sum_{j=2}^3 E j_i E j_k \geq 0$ , where the pure-state SEF monogamy relation in  $2 \times 2 \otimes 2^{N-2}$  systems is used. Because  $|\psi_{ABC}^i\rangle$  and  $|\psi_{ABC}^k\rangle$  are two arbitrary components, we can find that the second term in Eq. (20) is nonnegative.

### Appendix D: The calculation of bipartite multiqubit EOF in cavity-reservoir systems

In Eq. (28) of the main text, the multipartite entanglement indicators in tripartite pure and mixed states of cavity-

reservoir systems have the forms

$$\tau_{SEF(3)}(|\Phi_t\rangle_{c_1|c_2(r_1r_2)}) = E_f^2(|\Phi_t\rangle_{c_1|c_2(r_1r_2)}) - E_f^2(\rho_{c_1c_2}) - E_f^2(\rho_{c_1|r_1r_2}), \quad (D1)$$

$$\tau_{SEF(3)}^{(2)}(\rho_{c_1|r_1r_2}) = E_f^2(\rho_{c_1|r_1r_2}) - E_f^2(\rho_{c_1r_1}) - E_f^2(\rho_{c_1r_2}), \quad (D2)$$

where the calculation of bipartite three-qubit EOF  $E_f(\rho_{c_1|r_1r_2})$  is a key step for the application of these indicators. According to the Koashi-Winter formula [19], the EOF can be obtained via quantum discord and we have

$$E_f(c_1|r_1r_2) = D(c_1|c_2) + S(c_1|c_2), \quad (D3)$$

where  $S(c_1|c_2) = S(c_1c_2) - S(c_2)$  is the direct quantum generalization of conditional entropy [34], with  $S(\rho_x) = -\sum \lambda_i \log_2 \lambda_i$  being the von Neumann entropy, and the quantum discord of two cavity photons is

$$D(c_1|c_2) = \min_{\{E_{c_2}^k\}} \sum_k p_k S(c_1|E_{c_2}^k) - S(c_1|c_2), \quad (D4)$$

where the first term is the measurement-induced quantum conditional entropy [34] with the minimum runs over all the positive operator-valued measures. Chen *et al.* presented an effective method for calculating quantum discord and choosing optimal measurement [47]. After some analysis, we find that the optimal measurement for the quantum discord  $D(c_1|c_2)$  is  $\sigma_x$ . Then, according to Eq. (D3), we can derive

$$E_f(\rho_{c_1|r_1r_2}) = -\eta_1 \log_2 \eta_1 - (1 - \eta_1) \log_2 (1 - \eta_1) \quad (D5)$$

where the parameter  $\eta_1 = [1 - (1 - 4\beta^2\xi^2\chi^2)^{1/2}]/2$ .

Similarly, for the multipartite entanglement indicators shown in Fig. 2(b)-2(d), we can also derive the relevant multiqubit EOF via quantum discord. After some deduction, we can get

$$\begin{aligned} E_f(\rho_{c_1|c_2r_1}) &= -\eta_2 \log_2 \eta_2 - (1 - \eta_2) \log_2 (1 - \eta_2), \\ E_f(\rho_{r_1|c_1c_2}) &= -\eta_3 \log_2 \eta_3 - (1 - \eta_3) \log_2 (1 - \eta_3), \\ E_f(\rho_{r_1|r_2c_1}) &= -\eta_4 \log_2 \eta_4 - (1 - \eta_4) \log_2 (1 - \eta_4), \end{aligned} \quad (D6)$$

with the parameters being

$$\begin{aligned} \eta_2 &= \{1 - [1 - 4\beta^2\xi^2(\beta^2 + \xi^2 - 2\beta^2\xi^2)]^{1/2}\}/2, \\ \eta_3 &= [1 - (1 - 4\beta^2\xi^2\chi^2)^{1/2}]/2, \\ \eta_4 &= \{1 - [1 - 4\beta^2\chi^2(\beta^2 + \chi^2 - 2\beta^2\chi^2)]^{1/2}\}/2, \end{aligned} \quad (D7)$$

respectively.

## Appendix E: Proof of theorem 4

In a multipartite pure state of  $2 \otimes d_2 \otimes d_3 \cdots \otimes d_{N-1} \otimes d_N$  systems, the monogamy relation of the SEF is

$$\begin{aligned} E_f^2(|\Psi\rangle_{A_1|\tilde{A}_2\cdots\tilde{A}_N}) &= \sum_i E_f^2(\rho_{A_1\tilde{A}_i}) \\ &= E_f^2(C_{A_1|\tilde{A}_2\cdots\tilde{A}_N}^2) - \sum_i E_f^2(C_{A_1\tilde{A}_i}^2) \\ &= k_1 C_{A_1|\tilde{A}_2\cdots\tilde{A}_N}^2 - \sum_i k_i C_{A_1\tilde{A}_i}^2 \\ &= k_1 (C_{A_1|\tilde{A}_2\cdots\tilde{A}_N}^2 - \sum_i C_{A_1\tilde{A}_i}^2) + \Gamma_1, \end{aligned} \quad (E1)$$

where the subscript  $i \in \{2, N\}$  and we have used Theorem 1 in the main text in the first equality; the relations  $k_1 \geq k_i$ , with  $k_1 = E_f^2(C_{A_1|\tilde{A}_2\cdots\tilde{A}_N}^2)/C_{A_1|\tilde{A}_2\cdots\tilde{A}_N}^2$  and  $k_i = E_f^2(C_{A_1\tilde{A}_i}^2)/C_{A_1\tilde{A}_i}^2$ , in the second equality; and the non-negative parameter  $\Gamma_1 = \sum_i (k_1 - k_i) C_{A_1\tilde{A}_i}^2$  in the last equality.

When the SC is monogamous in the multipartite pure state  $|\Psi\rangle_{A_1\tilde{A}_2\cdots\tilde{A}_N}$ , we have the parameter

$$\Gamma_2 = k_1 \cdot (C_{A_1|\tilde{A}_2\cdots\tilde{A}_N}^2 - \sum_i C_{A_1\tilde{A}_i}^2) \geq 0. \quad (E2)$$

Therefore, the monogamy relation in Eq. (E1) is

$$\begin{aligned} E_f^2(|\Psi\rangle_{A_1|\tilde{A}_2\cdots\tilde{A}_N}) &= \sum_i E_f^2(\rho_{A_1\tilde{A}_i}) \\ &= \Gamma_1 + \Gamma_2 \geq 0, \end{aligned} \quad (E3)$$

since both parameters  $\Gamma_i$  are nonnegative. Furthermore, for the mixed-state case, we have

$$\begin{aligned} E_f^2(\rho_{A_1|\tilde{A}_2\cdots\tilde{A}_N}) &= \sum_j E_f^2(\rho_{A_1\tilde{A}_j}) \\ &\geq (\sum_i \mathcal{E}1_i)^2 - \sum_j (\sum_i \mathcal{E}j_i)^2 \\ &= \sum_i (\mathcal{E}1_i^2 - \sum_j \mathcal{E}j_i^2) + \Theta \geq 0, \end{aligned} \quad (E4)$$

where, in the first inequality, we have used the optimal pure-state decomposition  $\rho_{A_1\tilde{A}_2\cdots\tilde{A}_N} = \sum_i p_i |\Psi^i\rangle\langle\Psi^i|$  for  $E_f(\rho_{A_1|\tilde{A}_2\cdots\tilde{A}_N})$ , with  $\mathcal{E}1_i = p_i E_f(|\Psi^i\rangle_{A_1|\tilde{A}_2\cdots\tilde{A}_N})$ , and the relation  $E_f(\rho_{A_1\tilde{A}_j}) \leq \sum_i \mathcal{E}j_i$ , with  $\mathcal{E}j_i = p_i E_f(\rho_{A_1\tilde{A}_j}^i)$ ; in the second equality, the first term is nonnegative due to the pure state monogamy property, and the second term  $\Theta = 2 \sum_i \sum_{k=i+1}^N (\mathcal{E}1_i \mathcal{E}1_k - \sum_{j=2}^N \mathcal{E}j_i \mathcal{E}j_k)$  is also nonnegative after an analysis similar to that in Appendix C. Therefore, we find that the SEF is monogamous in the multipartite systems when the SC obeys this property.

Next, we consider the situation where the SC is polygamous in multipartite systems,

$$C^2(\rho_{A_1|\tilde{A}_2\cdots\tilde{A}_N}) - \sum_j C^2(\rho_{A_1\tilde{A}_j}) \leq 0, \quad (E5)$$

which results in the SC also being polygamous in the pure state case. In this case, we have

$$\Gamma_2 = k_1 \cdot (C_{A_1|\tilde{A}_2\cdots\tilde{A}_N}^2 - \sum_i C_{A_1\tilde{A}_i}^2) < 0, \quad (\text{E6})$$

and then the monogamy relation in Eq. (E1) is

$$E_f^2(|\Psi\rangle_{A_1|\tilde{A}_2\cdots\tilde{A}_N}) - \sum_i E_f^2(\rho_{A_1\tilde{A}_i}) = \Gamma_1 - |\Gamma_2|, \quad (\text{E7})$$

which is monogamous when the parameter  $\Gamma_1$  is not less than the absolute value of the parameter  $\Gamma_2$ , *i.e.*,

$$\Gamma_1 \geq |\Gamma_2|. \quad (\text{E8})$$

Furthermore, when this monogamy relation of SEF in Eq. (E7) is satisfied, we can find that the mixed-state case holds via an analysis similar to that in Eq. (E4). Thus, we find that the SEF can be monogamous even if the SC is polygamous, and an example is shown in Eqs. (35) and (36) of the main text.

Combining the cases with the SC being monogamous and polygamous, we find that in multipartite  $2 \otimes d_2 \otimes d_3 \cdots \otimes d_{N-1} \otimes d_N$  systems, the monogamy property of SEF is superior to that of SC, which completes the proof of Theorem 4 in the main text.

#### Appendix F: Monogamy properties of SEF and SC in a $4 \otimes 2 \otimes 2$ quantum state

For the  $4 \otimes 2 \otimes 2$  quantum state  $|\Phi\rangle_{ABC}$  shown in Eq. (39) of the main text, the bipartite reduced state for subsystem  $AB$  can be written as

$$\rho_{AB} = \frac{1}{2}|\varphi_1\rangle\langle\varphi_1| + \frac{1}{2}|\varphi_2\rangle\langle\varphi_2|, \quad (\text{F1})$$

where the pure-state components are  $|\varphi_1\rangle = \alpha|00\rangle + \beta|11\rangle$  and  $|\varphi_2\rangle = \alpha|20\rangle + \beta|31\rangle$ , respectively. In an arbitrary pure state decomposition of  $\rho_{AB}$ , the pure-state component has the form

$$|\tilde{\varphi}_i\rangle_{AB} = a_i|\varphi_1\rangle + e^{-i\gamma}\sqrt{1-a_i^2}|\varphi_2\rangle \quad (\text{F2})$$

for which the reduced density matrix  $\rho_B^i = \text{diag}\{\alpha^2, \beta^2\}$ . Therefore, according to the definition of EOF in Eq. (3) of the main text, we have

$$E_f(\rho_{AB}) = S(B) = -\alpha^2 \log_2 \alpha^2 - \beta^2 \log_2 \beta^2. \quad (\text{F3})$$

Similarly, for the reduced quantum state  $\rho_{AC}$ , we have  $E_f(\rho_{AC}) = 1$ . Moreover, the reduced quantum state of subsystem  $A$  is  $\rho_A = \text{diag}\{\alpha^2/2, \beta^2/2, \alpha^2/2, \beta^2/2\}$ , from which we get

$$E_f(|\Phi\rangle_{A|BC}) = S(A) = S(B) + 1. \quad (\text{F4})$$

Thus, the monogamy property of SEF is

$$\begin{aligned} M(SEF) &= E_f^2(A|BC) - E_f^2(AB) - E_f^2(AC) \\ &= S^2(A) - S^2(B) - 1^2 \\ &= 2S(B), \end{aligned} \quad (\text{F5})$$

which is nonnegative, and therefore, the SEF is monogamous.

Next, we analyze the distribution of SC in this quantum state. For the bipartite  $4 \otimes 2$  mixed state  $\rho_{AB}$ , its concurrence is defined by the convex roof extension [39, 63]

$$C(\rho_{AB}) = \min \sum_i p_i C(|\psi^i\rangle_{AB}), \quad (\text{F6})$$

where the minimum runs over all the pure-state decompositions and the pure-state concurrence is  $C(|\psi^i\rangle_{AB}) = \sqrt{2(1 - \text{Tr}\rho_{B_i}^2)}$  [64]. According to the property of pure state decomposition in Eq. (F2), we can derive

$$C_{AB}^2 = 4\alpha^2\beta^2. \quad (\text{F7})$$

In a similar way, we can obtain  $C_{AC}^2 = 1$ . Moreover, the concurrence in the partition  $A|BC$  is

$$C_{A|BC}^2 = 2(1 - \text{Tr}\rho_A^2) = 2 - \alpha^4 - \beta^4, \quad (\text{F8})$$

and then the monogamy relation of SC is

$$\begin{aligned} M(SC) &= C_{A|BC}^2 - C_{AB}^2 - C_{AC}^2 \\ &= (2 - \alpha^4 - \beta^4) - 4\alpha^2\beta^2 - 1 \\ &= -2\alpha^2\beta^2, \end{aligned} \quad (\text{F9})$$

which is polygamous. In Fig. 4, the parameters are chosen to be  $\alpha = \cos\theta$  and  $\beta = \sin\theta$ , and the distributions  $M(SEF)$  and  $M(SC)$  are plotted as functions of parameter  $\theta$ , which illustrates the different entanglement properties of SEF and SC.
